#### Stack

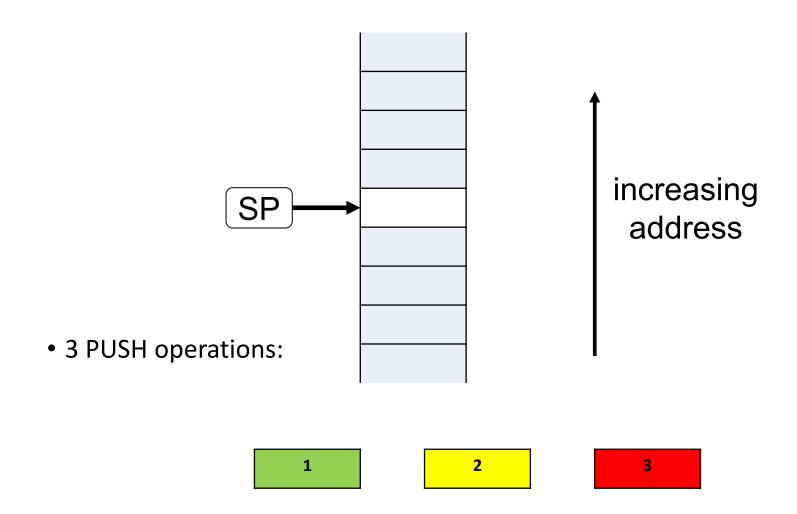

- A stack is a Last In-First Out (LIFO) queue.
- Data is pushed (written) to and popped (read) from the top of the stack.
- The stack pointer contains the address of the top of the stack.

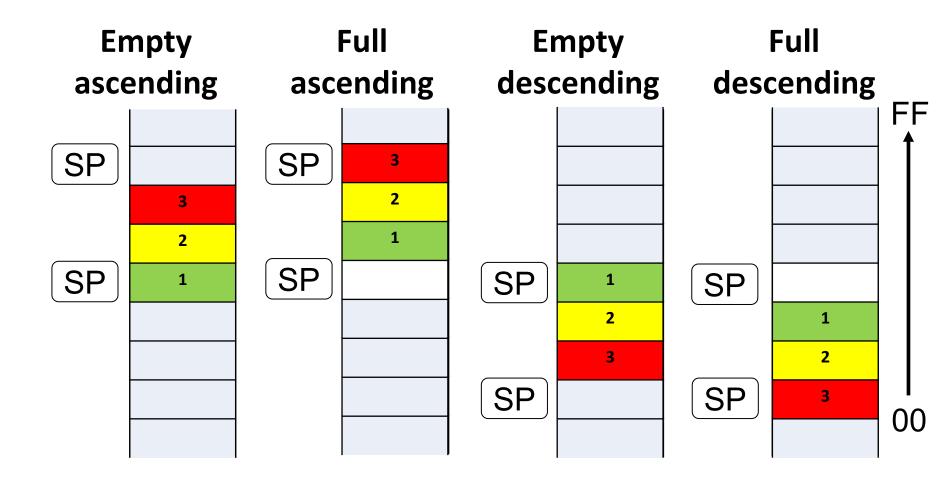

# Types of stack

- Stack pointer is updated after push:
  - descending stack: the address of the top of the stack decreases after a push
  - ascending stack: the address of the top of the stack increases after a push
- Content of the entry at the top of the stack:
  - empty stack: the stack pointer points to the entry where new data will be pushed
  - full stack: the stack pointer points to the last pushed entry.

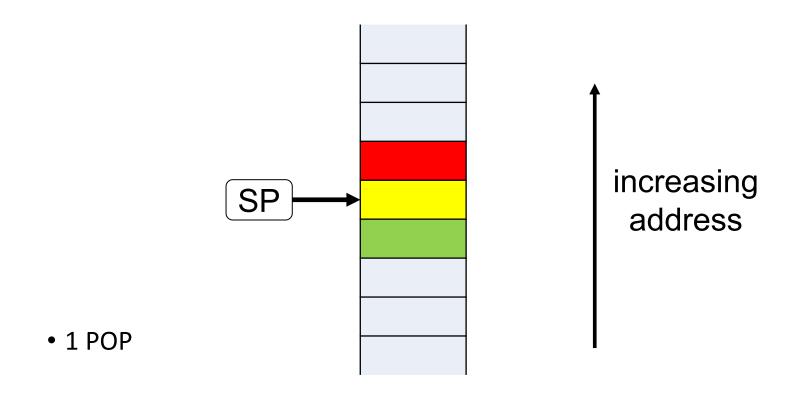

# Example with PUSH: initial state

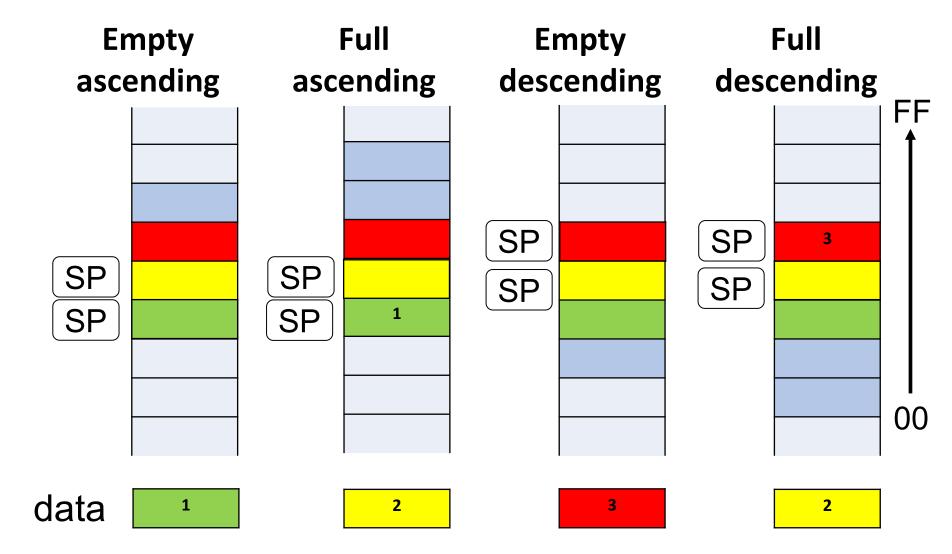

# Example after 3 PUSH operations

# Example with POP: initial state

# Example after 1 POP

#### LDM and STM

• They transfer one or more words:

```
LDM\{xx\}/STM\{xx\} < Rn>\{!\}, < regList>
```

- Rn is the base register
- xx specifies the addressing mode, i.e., how and when Rn is updated during the instruction
- at the end of the instruction:
  - with !, Rn is set to the updated value
  - without !, Rn is set to the initial value
- regList is a list of registers.

# List of registers

- Consecutive registers are indicated by separating the initial and final registers with a dash
- Non consecutive registers are separated with a comma.
- Example: {r0-r4, r10, LR} indicates r0, r1, r2, r3, r4, r10, r14.
- SP can not appear in the list.
- PC can appear only with LDM and only if LR is missing in the list.

# Order of registers in the list

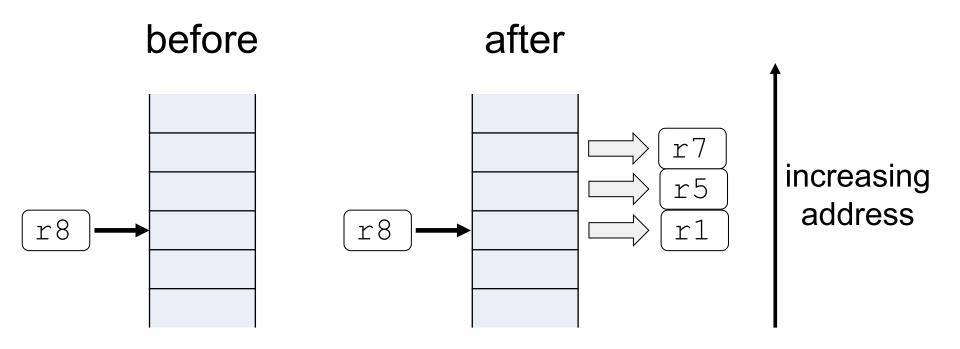

- The written order of registers does not matter.
- Registers are automatically sorted in increasing order:
  - the lowest register is stored into / loaded from the lowest memory address
  - the highest register is stored into / loaded from the highest memory address
- Example: {r8, r1, r3-r5, r14} indicates r1, r3, r4, r5, r8, r14.

# Addressing modes

- IA: increment after (default)
  - The memory is accessed at the address specified in the base register
  - 2. The base register is incremented by 1 word (4 bytes)
  - 3. if there are other registers in the list, go to 1.
- DB: decrement before
  - 1. The base register is decremented by 1 word (4 bytes)
  - The memory is accessed at the address specified in the base register
  - 3. if there are other registers in the list, go to 1.

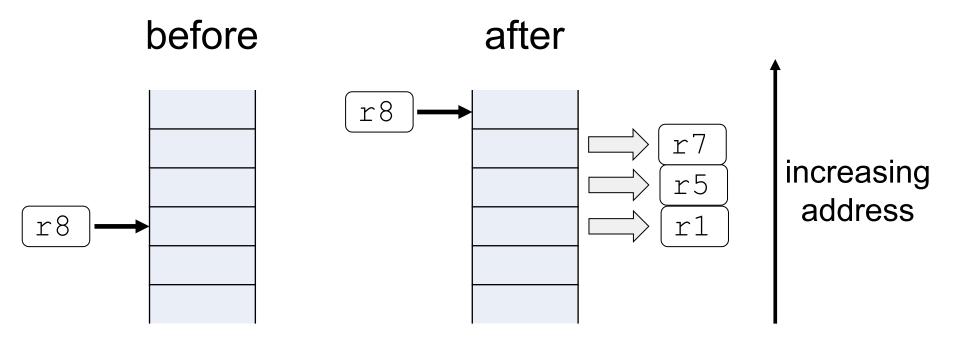

# LDMIA: an example

```
LDMIA r8, {r1, r5, r7}
LDM r8, {r1, r5, r7}
```

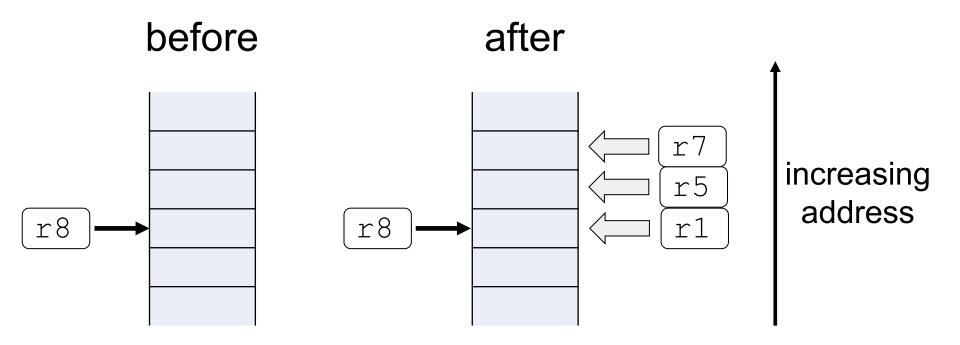

# LDMIA with '!': an example

```
LDMIA r8!, {r1, r5, r7}
LDM r8!, {r1, r5, r7}
```

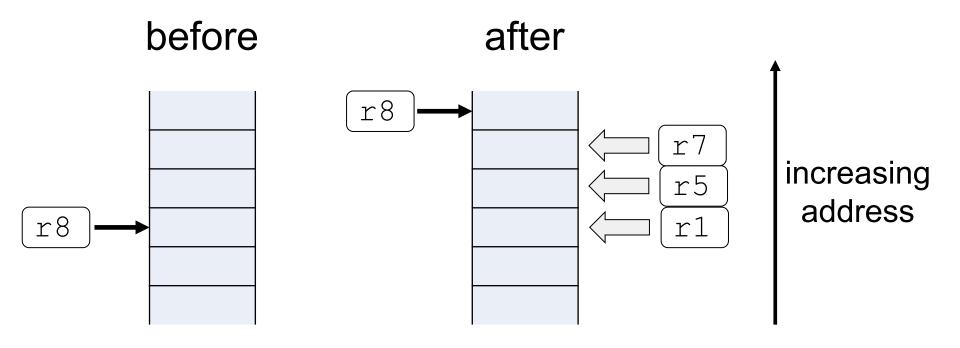

# STMIA: an example

```
STMIA r8, {r1, r5, r7}
STM r8, {r1, r5, r7}
```

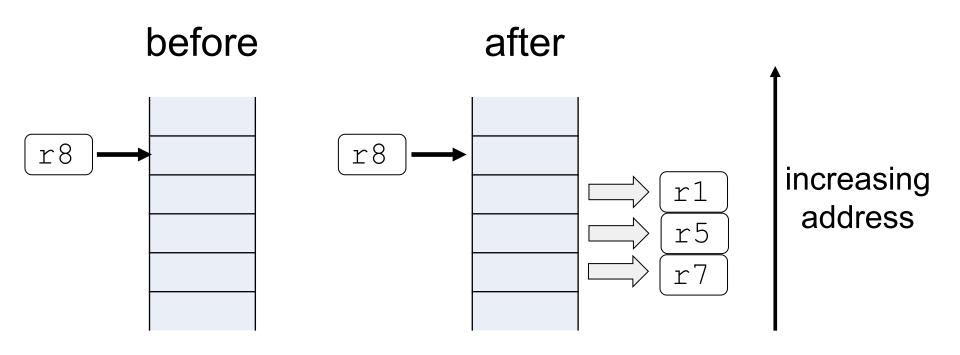

# STMIA with '!': an example

```
STMIA r8!, {r1, r5, r7}
STM r8!, {r1, r5, r7}
```

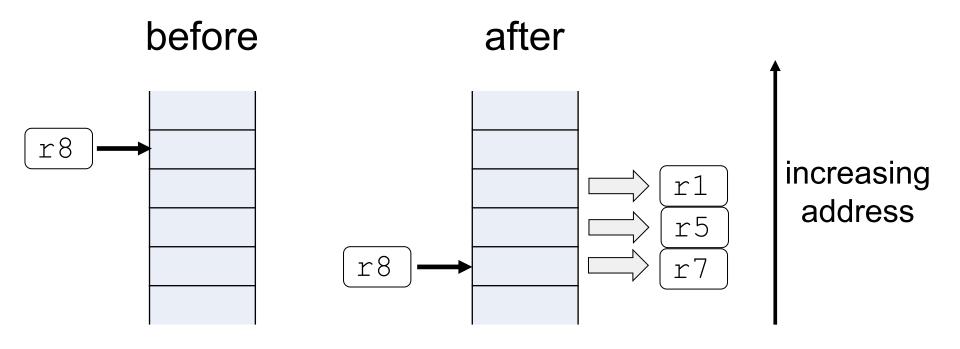

# LDMDB: an example

LDMDB r8, {r1, r5, r7}

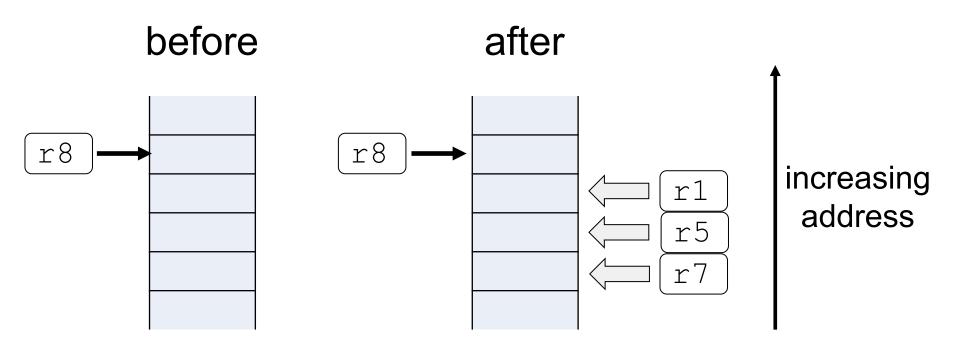

# LDMDB with '!': an example

LDMDB r8!, {r1, r5, r7}

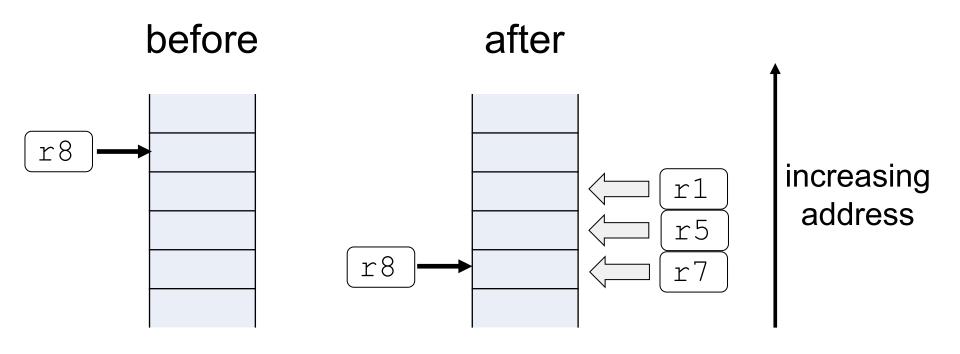

# STMDB: an example

STMDB r8, {r1, r5, r7}

# STMDB with '!': an example

STMDB r8!, {r1, r5, r7}

# Supported types of stack

• Stack-oriented suffixes can be used instead of increment/decrement and before/after.

Stack type	PUSH	POP
Full descending	STMDB STMFD	LDM LDMIA LDMFD
Empty ascending	STM STMIA STMEA	LDMDB LDMEA

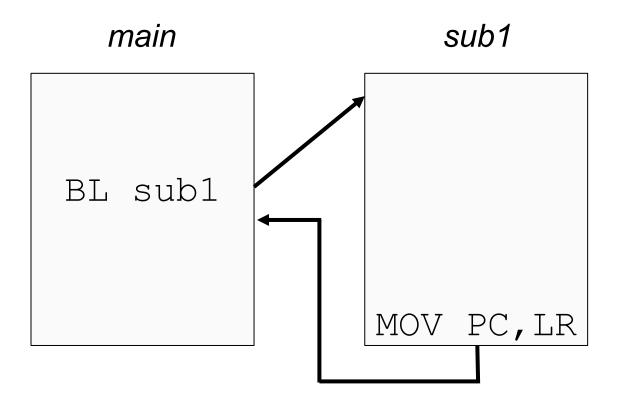

#### PUSH and POP

- PUSH and POP instructions facilitate the use of a full descending stack.
- PUSH <regList> is the same as STMDB SP!, <regList>
- POP <regList> is the same as LDMIA SP!, <regList>

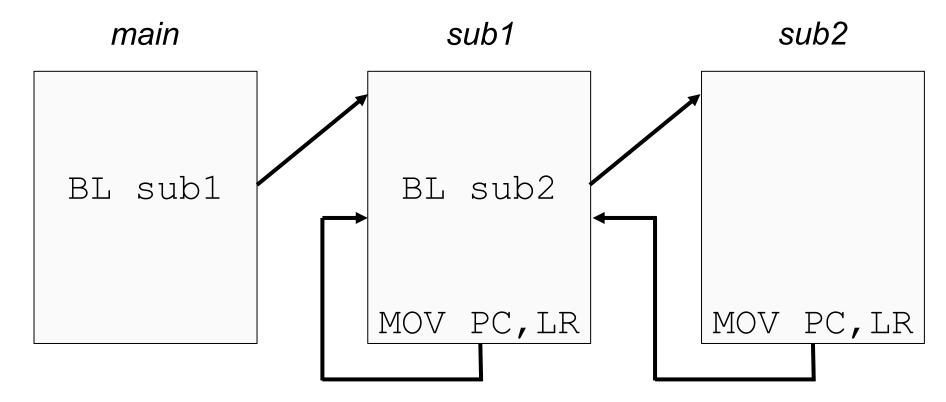

#### Subroutine

- A subroutine is called with BL and BLX.
- BL < label > and BLX < Rn >:
  - ullet write the address of the next instruction to LR
  - write the value of label or Rn to PC
- A reentrant procedure ends with a branch to the address stored in LR.
- Optionally, the begin and end of a subroutine can be indicated with the directives PROC/FUNCTION and ENDP/ENDFUNC.

## Call to subroutine

#### Nested calls to subroutines

- When *sub1* calls *sub2*, LR is overwritten.
- *sub1* is not able to return to *main*.

#### Nested calls to subroutines

- Besides changing LR when called, *sub2* may also change the value of registers used in *sub1*.
- Every subroutine should save LR and the other used registers as first instruction:

```
PUSH {regList, LR}
```

• At the end, the subroutine restores PC and the initial value of the used registers:

```
POP {regList, PC}
```

# Passing parameters and result

- There are three approaches:
  - in registers
  - by reference, i.e., a register with an address in memory
  - on the stack
- Example: a main routine calls a subroutine for computing the absolute difference of two unsigned numbers.

# Passing parameters in registers

```
MOV r0, #0x34
MOV r1, #0xA3
BL sub1
; r2 contains the result
...
stop B stop
...
```

# Passing parameters in registers

```
sub1 PROC
PUSH {LR}
CMP r0, r1
SUBHS r2, r0, r1
SUBLO r2, r1, r0
POP {PC}
ENDP
```

# Passing parameters by reference

```
MOV r0, #0x34
    MOV r1, \#0xA3
    LDR r3, =mySpace
    STMIA r3, {r0, r1}
    BL sub2
                      By reference
                      parameter
    LDR r2, [r3]
    ; r2 contains the result
stop B stop
```

# Passing parameters by reference

```
sub2
        PROC
        PUSH {r2, r4, r5, LR}
        LDMIA r3, {r4, r5}
        CMP r4, r5
        SUBHS r2, r4, r5
        SUBLO r2, r5, r4
        STR r2, [r3]
        POP {r2, r4, r5, PC}
        ENDP
```

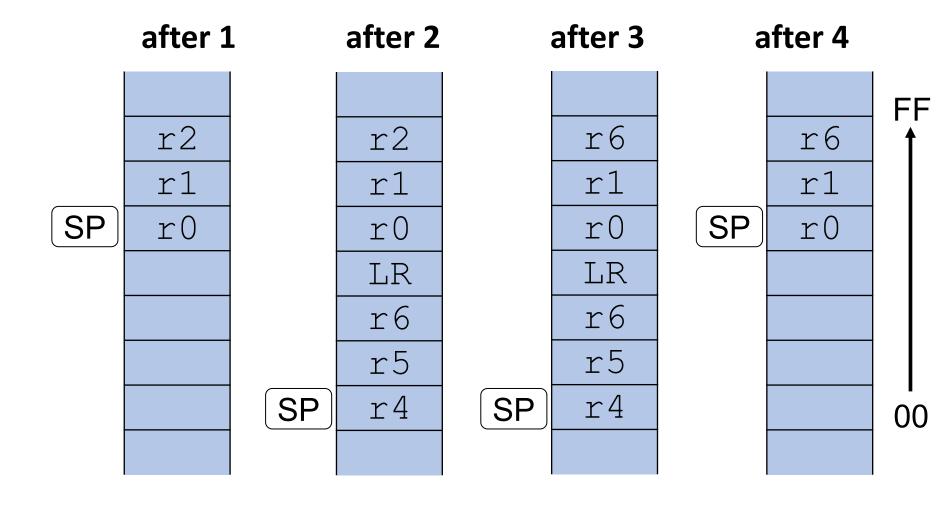

# Passing parameters on the stack

```
MOV r0, #0x34
    MOV r1, \#0xA3
   PUSH {r0, r1, r2}
                                  Prepare arguments
    BL sub3
                                  and leave space for
                                  results
    POP {r0, r1, r2}
    ; r2 contains the result
stop B stop
```

# Passing parameters on the stack

```
sub3
          PROC
        (2) PUSH {r6, r4, r5, LR}
          LDR r4, [sp, #16]
                                         Save all registers
                                         that are used to
          LDR r5, [sp, #20]
                                         hold the values of a
          CMP r4, r5
                                         routine's local
                                         variables
          SUBHS r6, r4, r5
          SUBLO r6, r5, r4
                                         Saves results
       (3)STR r6, [sp, #24]
        4)POP {r6, r4, r5, PC}
                                         Restore registers
                                         content, update PC
          ENDP
                                         to LR to return to
                                         the caller function
```

#### Elements in the stack

# ABI – Application Binary Interface

- In computer software, an Application Binary Interface (ABI) is an interface between two binary program modules;
  - often, one of these modules is a library or operating system facility,
     and
  - the other is a program that is being run by a user
- A common aspect of an ABI is the <u>calling convention</u>, which determines how data is provided as input to or read as output from computational routines.

#### ABI standard for ARM

ABI for the ARM Architecture (Base Standard)

# Application Binary Interface for the ARM® Architecture

The Base Standard

Document number: A
Date of Issue: 1

ARM IHI 0036B, current through ABI release 2.09 10<sup>th</sup> October 2008, reissued 30<sup>th</sup> November 2012

#### **Abstract**

This document describes the structure of the Application Binary Interface (ABI) for the ARM architecture, and links to the documents that define the base standard for the ABI for the ARM Architecture. The base standard governs inter-operation between independently generated binary files and sets standards common to ARM-based execution environments.

#### Keywords

ABI for the ARM architecture, ABI base standard, embedded ABI

# ABI components

# Procedure Call Standard for the ARM architecture

• The *Procedure Call Standard for the ARM architecture* [AAPCS] specifies the use of the run-time stack, and the stack invariants that must be preserved.

AAPCS Procedure Call	CPPABI - C++ ABI for the ARM architecture		AAELF – ELF for the ARM architecture	AADWARF – DWARF for the ARM	RTABI – Run-time ABI for the ARM

## ABI and other definitions in AAPCS

Term	Meaning	
ABI	Application Binary Interface:	
	<ol> <li>The specifications to which an executable must conform in order to execute in a specific execution environment. For example, the Linux ABI for the ARM Architecture.</li> </ol>	
	<ol> <li>A particular aspect of the specifications to which independently produced relocatable files must conform in order to be statically linkable and executable. For example, the C++ ABI for the ARM Architecture, the Run-time ABI for the ARM Architecture, the C Library ABI for the ARM Architecture.</li> </ol>	
ARM-based	based on the ARM architecture	
EABI	An ABI suited to the needs of embedded (sometimes called <i>free standing</i> ) applications.	
Routine, subroutine	A fragment of program to which control can be transferred that, on completing its task, returns control to its caller at an instruction following the call. <i>Routine</i> is used for clarity where there are nested calls: a routine is the <i>caller</i> and a subroutine is the <i>callee</i> .	
Procedure	A routine that returns no result value.	
Function	A routine that returns a result value.	
Activation stack, call-frame stack	The stack of routine activation records (call frames).	
Activation record, call frame		

Register	Synonym	Special	Role in the procedure call standard	
r15		PC	The Program Counter.	
r14		LR	The Link Register.	
r13		SP	The Stack Pointer.	
r12		IP	The Intra-Procedure-call scrat	ch register.
r11	<b>v</b> 8		Variable-register 8.	n he freely used to
r10	ν7		Variable-register /.	an be freely used to
г9		v6 SB TR	Platform register. The meaning of this register	ed by the platform standard.
r8	<b>v</b> 5		Variable-register 5.	If there are more
r7	v4		Variable register 4.	than 4 formal
r6	<b>v</b> 3		Variable register 3.	
r5	v2		Variable register 2.	arguments, they
r4	v1		Variable register 1.	have to be saved in
r3	a4		Argument / scratch register 4.	the stack
r2	a3		Argument / scratch register 3.	
r1	a2		Argument / result / scratch reg	jister 2.
r0	a1		Argument / result / scratch reg	jister 1.

Table 2, Core registers and AAPCS usage

# Passing arguments

• The first four registers r0-r3 (a1-a4) are used to pass argument values into a subroutine and to return a result value from a function.

• A subroutine must preserve the contents of the registers r4-r8, r10, r11 and SP

Callee saving of caller status

- The base standard provides for passing arguments in core registers (r0-r3) and on the stack.
  - For subroutines that take a small number of parameters, only registers are used, greatly reducing the overhead of a call.

Caller saving to preserve status of non-volative register values

# STACK management

- The stack implementation is *full-descending*, with the current extent of the stack held in the register SP (r13).
- The stack will, in general, have both a base and a limit
  - though in practice an application may not be able to determine the value of either.

Full descending	STMDB STMFD	LDMIA
		LDMFD

#### Local variables in stack – stack frame

- It is possible to create local variables on the stack
  - in the same way we stored also the saved values there, by simply subtracting the number of bytes required by each variable from the stack pointer.
  - This does not store any data in the variables, it simply sets aside memory that we can use.
